# Introduction

Authors present a framework (model and data processing tools) for solving three **Information Extraction** tasks:

- **Named Entity Recognition (NER)**
- **Relation Extraction (RE)**
- **Event Extraction (EE)**

and also they solve auxiliary **Coreference Resolution (CR)** task to enhance model inference.

# Introduction

## Def. 1

**Text Span** - a continuous sequence of tokens or their embeddings (vector representations of tokens).

## Def. 2

**Span Graph** - a graph of entities with edges defining coreferences, relations and events.

# Problem Definition

Given a document  $D$  represented as a sequence of words, we derive  $S = \{S_1, \dots, S_T\}$ , the set of all possible within-sentence text spans.

Then, our goal is to solve:

- CR task: predict antecedent  $c_i$  for each span  $s_i$
- NER task: predict entity type  $e_i$  for each span  $s_i$ ,
- RE task: predict relation  $r_{ij}$  for each pair of within-sentence spans  $(s_i, s_j)$ ,
- EE task: assign an event trigger label  $d_i$  for each predicted entity and predict event arguments  $a_{ij}$  for all spans  $s_j$  in the same sentence as  $d_i$ .

# Global Context

One of the toughest problems to address during solving these tasks is the problem of **global context modeling**. To make use of distant links between entities in text is not a trivial problem. Authors try to address this by employing several ideas.

# Highlights

What key ideas authors employ in their work?

- Using **Multi-Task Learning**
- Using **pre-trained BERT as text encoder**. BERT creates contextual embeddings and eliminates need for hand-crafted features extraction. Authors test two options of using BERT: for fine-tuning alone, and with biLSTM after BERT.
- Using **Span Graph** to incorporate global context information, that is outside of text window scope of encoder.
- Using of **coreferences between entities** to further enhance global context modeling

# Architecture Description

There are 4-layer structure of model inside framework:

- **Token encoding:** several sentences are fed to BERT
- **Span enumeration:** BERT embeddings are enumerated and coreferences are iteratively resolved and updated.
- **Span graph propagation:** iterative inference for relations and propagation of this information, as well as propagation of corefs and update of graph.
- **Multi-task classification:** final inference stage.  
Re-contextualized span representations or their pairs are supplied to two-layer FFNN scoring function.

# Training

The loss function for training process is defined as weighted sum of log-likelihood for all tasks (because of multi-task learning):

$$\sum_{(D, R^*, E^*, C^*) \in \mathcal{D}} \left\{ \lambda_E \log P(E^* | C, R, D) \quad (5) \right. \\ \left. + \lambda_R \log P(R^* | C, D) + \lambda_C \log P(C^* | D) \right\}$$

# Datasets

Authors tested their model on several datasets from various domains:

|         | Domain  | Docs | Ent | Rel | Trig | Arg |
|---------|---------|------|-----|-----|------|-----|
| ACE05   | News    | 511  | 7   | 6   | -    | -   |
| ACE05-E | News    | 599  | 7   | -   | 33   | 22  |
| SciERC  | AI      | 500  | 6   | 7   | -    | -   |
| GENIA   | Biomed  | 1999 | 5   | -   | -    | -   |
| WLP     | Bio lab | 622  | 18  | 13  | -    | -   |

Table 8: Datasets for joint entity and relation extraction and their statistics. *Ent*: Number of entity categories. *Rel*: Number of relation categories. *Trig*: Number of event trigger categories. *Arg*: Number of event argument categories.

# Experiments and Results

| Dataset      | Task     | SOTA        | Ours        | $\Delta\%$ |
|--------------|----------|-------------|-------------|------------|
| ACE05        | Entity   | 88.4        | <b>88.6</b> | 1.7        |
|              | Relation | 63.2        | <b>63.4</b> | 0.5        |
| ACE05-Event* | Entity   | 87.1        | <b>90.7</b> | 27.9       |
|              | Trig-ID  | 73.9        | <b>76.5</b> | 9.6        |
|              | Trig-C   | 72.0        | <b>73.6</b> | 5.7        |
|              | Arg-ID   | <b>57.2</b> | 55.4        | -4.2       |
|              | Arg-C    | 52.4        | <b>52.5</b> | 0.2        |
| SciERC       | Entity   | 65.2        | <b>67.5</b> | 6.6        |
|              | Relation | 41.6        | <b>48.4</b> | 11.6       |
| GENIA        | Entity   | 76.2        | <b>77.9</b> | 7.1        |
| WLPC         | Entity   | 79.5        | <b>79.7</b> | 1.0        |
|              | Relation | 64.1        | <b>65.9</b> | 5.0        |

**Figure:** DYGLIE++ achieves state-of-the-art results. Test set F1 scores of best model, on all tasks and datasets.

# Keynotes

- The largest gains from Coreference propagation are on the CS research abstracts of SciERC, which have lots of coreferences, acronyms and abbreviations.
- Relation propagation improves relation extraction performance over pre-trained BERT, but does not improve fine-tuned BERT. Probably, because relations predicted only within same sentence.

# Keynotes

- Benefits of cross-sentence context with BERT: model achieved best results across all relation and extraction tasks with 3-sentence window.
- On Event Extraction, BERT fine-tuning decreases performance by 1.6 F1 on average across tasks. Probably, because of task sensitivity to hyperparameters choice - there were cases when trigger detector begun overfitting before the argument detector had finished training.

# Conclusion

The authors pushed forward state-of-the-art solutions to three main tasks of Information Extraction. The paper proves that multi-task learning can be reasonable way to asses global context modeling problem.

Thanks for your attention!
